1 | An Overview of the EASYINTERFACE Framework

The EASYINTERFACE framework provides a simple way to build interfaces, e.g, a web-interface or an Eclipse plug-in, for tools written in (almost) any programming language. Moreover, it does not require the programmer to be familiar with any GUI library or web programming. Roughly, the only requirement is that the application can be executed from a command-line and that its output goes to the standard output. With the EASYINTERFACE framework we achieve the goal: *build an application once, and get several sophisticated interfaces for free*. In the rest of this chapter we explain the different components of this framework, and how they are combined to achieve the above goal. As will be noticed later, the EASYINTERFACE framework was developed with program analysis tools in mind, this is why the graphical user interfaces that it provides are basically developing environments that allow editing programs, etc.

1.1 The Architecture of EASYINTERFACE

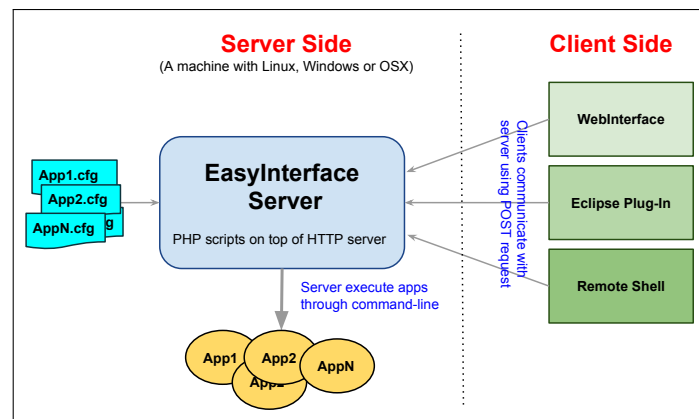

Figure 1.1: The Architecture of the EASYINTERFACE Framework

The architecture of the EASYINTERFACE framework is depicted in Figure 1.1. It includes two main components: (1) *server side*: a machine with several applications (the circles App1, App2, etc.) that can be executed from a command-line and produce their output to the standard output. These are the applications that we want to make available for the outside world, i.e., execute them as services on the internet; and (2) *client side*: several clients that makes it easy to communicate with the server side to execute application, etc. In what follows we start explaining the inner components of the server side, and which problems they solve, and then we move on to explain the client side.

1.1.1 The Server Side

The problem that we want to solve at the server side is:

provide a uniform way for accessing the locally installed application as services (i.e., through the internet).

This problem is solved by the EASYINTERFACE server, which is collection of PHP programs that run on an HTTP server. The EASYINTERFACE server allows specifying how a local applications can be executed and which parameter they take using simple configuration files (App1.cfg, App2.cfg, etc.). For example, the following is a snippet of such configuration file:

```

<app id='myapp' visible="true">
  ...
  <execinfo method="cmdline">
    <cmdlineapp>./default/myapp.sh _ei_parameters </cmdlineapp>
  </execinfo>
  <parameters prefix = "-" check="false">
    ...
    <selectone name="c">
      <option value="1" />
      <option value="2" />
    </selectone>
  </parameters>
</app>

```

This XML defines an application that has a unique identifier **myapp**. The **cmdlineapp** tag is a template that describes how to execute the application from a command-line. Here **_ei_parameters** is a template parameter that will be replaced by an appropriate value. The **parameters** tag includes a list of parameters accepted by the application. For example, there is a parameter called “c” that can take one of the values 1 or 2. Once the configuration file is installed on the EASYINTERFACE server, anyone can access the application using an HTTP POST request that include something similar to the following:

```

{
  command: "execute",
  app_id: "myapp",
  parameters: {
    c: ["1"],
    ...
  },
  ...
}

```

When the EASYINTERFACE server receives such a request, it generates a corresponding command-line (according to what is describe din the configuration file), executes it, and redirect the standard output back to the client.

1.2 The Clients Side

Although now we have a relatively easy way to execute application on the server side, we still need to make HTTP POST requests, etc. We are interesting replacing this by (graphical) user interfaces that does so automatically. For this, we provide clients that allow the user to select an application to execute, set the values of the corresponding parameters and then it automatically generate the corresponding request and communicate with the EASYINTERFACE server.

The first client is a web-interface that can be executed in a browser and looks like an environment for developing programs, the second is an Eclipse-plugin that runs inside the Eclipse IDE, and the last we call a remote-shell that can be used from a command-line. Now since the web-client and the Eclipse plugin include a developing environment, it would be nice to provide away such that apps can view their output in a graphical way (e.g., open dialog box, highlight code lines, add markers in the editor). For this, the EASYINTERFACE framework defines a text-based output language that can be used by the applications to describe their output, and the clients include an interpreter that transform this text-based command into graphical element.

2 | A Quick Guide to EASYINTERFACE

This chapter provides a quick introduction on *how to integrate an application in the EASYINTERFACE framework*. In particular, we develop a simple application, integrate it in the EASYINTERFACE server, and try it out through the web-client. The presentation is incremental, we start with a simple application and in each step we add more features to demonstrate the different parts of the EASYINTERFACE framework. In our explanation we assume that a Unix based operating system is used, however, we comment on how to do the analog operations on Windows when they are different. Note that in this chapter we only use the web-client, for other clients refer to Chapter ???. We assume that EASYINTERFACE is already installed and working, which can be done following the instructions in “INSTALL.md”.

Let us start by trying some demo applications that are available by default in the web-client. If you visit `http://localhost/ei/clients/web`, you should get a page similar to the one shown in Figure ??. At the top part of this page you can see a button with the label `Apply`, and to its right a combo-box with several items `Test-0`, `Test-1`, etc. These items correspond to applications available in the web-client. To the left of `Apply` there is a button with the label `Settings`, if you click it you will see that each `Test-i` has also some parameters that can be set to some value. Note that, by default, the web-client is configured to connect to the EASYINTERFACE server at `http://localhost/ei/server` and ask for all applications, together with their corresponding parameters, that are available at that server. Note also that application `Test-i` actually corresponds to the bash-script `server/bin/default/test-i.sh`, and that its configuration file is `server/config/default/test-i.cfg` (later you will understand the details of such configuration files).

If you select an application, from the combo-box, and click on `Apply`, the web-client sends a request to the server to execute this application. The request includes also the current values of the parameters (those in the settings section) and the file that is currently active in the editor area. The server, in turn, executes the corresponding program, i.e., the bash-script `server/bin/default/test-i.sh` in this case, and redirects its output back to the web-client. The web-client will either print this output in the console area, or view it graphically if it uses the EASYINTERFACE output language. Execute the demo applications just to get an idea on which graphical output we are talking about (e.g., highlight text, markers). In the rest of this chapter we explain, step by step, how to add your own application to EASYINTERFACE.

2.1 Add Your First Application to the EASYINTERFACE Server

When we add an application to the EASYINTERFACE server it will appear automatically in the applications menu of the web-client (unless you have changed the configuration of the web-client already!). This is because the web-client is configured to retrieve all applications that are installed on the server that is available at `http://localhost/ei/server`. Let us add a simple “Hello World” application.

We start by creating a bash-script that represents the executable of our application (it could be any other executable). We will place this bash-script in the directory `server/bin/default` together with the `test-i.sh` scripts, however, this is not obligatory and it can be placed anywhere in the file system as far as the HTTP server can access it. Create a file `myapp.sh` in `server/bin/default` with the following content:

```
1 #!/bin/bash
2
3 echo "Hello World!"
```

As you can see, it is a simple program that prints “Hello World” on the standard output. Later we will see how to pass input to this application and how to generate more sophisticated output. Change the permissions of `myapp.sh` by executing the following (on Windows this is typically not needed):

```
> chmod -R 755 myapp.sh
```

Execute `myapp.sh` (in a shell) to make sure that it works correctly before proceeding to the next step.

Next we will configure the server to recognize our application. Create a file `myapp.cfg` in the directory `server/config/default` with the following content (we could place this file anywhere under `server/config` not necessarily in `default`):

```
<app visible="true">
  <appinfo>
    <acronym>MFA</acronym>
    <title>My First Application</title>
    <desc>
      <short>A simple EI application</short>
      <long>A simple application that I've done using the EasyInterface Framework</long>
    </desc>
  </appinfo>
  <apphelp>
    <content format='html'>
      This is my first <b>EasyInterface</b> application!
    </content>
  </apphelp>
  <execinfo method="cmdline">
    <cmdlineapp>./default/myapp.sh</cmdlineapp> %   are used to escape
  </execinfo>
</app>
```

Let us explain the meaning of the different elements of this configuration file. The `app` tag is used to declare an EASYINTERFACE application, and its `visible` attribute tells the server to list this application when someone asks for the list of installed applications. Changing this value to `"false"` will make the application "hidden" so only those who know its identifier can use it. The `appinfo` tag provides general information about the application, this will be used by the clients to show the application name, etc. The `apphelp` tag provides some usage information about the application, or simply provide a link to another page where such information can be found. The actual content goes inside the `content` tag, which is HTML as indicated by the `format` attribute (use 'text' for plain text). The most important part is the `execinfo` tag, which provides information on how to execute the application. The attribute `method` declares that this application should be executed from a command-line as described in `cmdlineapp`. The text inside `cmdlineapp` is interpreted as a command-line *template*, such that when the server is requested to execute the corresponding application it will simply execute this command-line and redirect its output back to the client. Later you will understand why we call it *template*. Note that before executing the script, the server changes the current directory to `server/bin` and thus the command-line should be relative to `server/bin`.

Next we add the above configuration file to the server. This is done by adding the following line to `server/config/default/apps.cfg` (inside the `apps` tag):

```
<app id="myapp" src="default/myapp.cfg" />
```

Here we tell the server that we want to install an application as defined in `myapp.cfg`, and we want to assign it the *unique* identifier `"myapp"`. This identifier will be mainly used by the server and the clients when they communicate, we are not going to use it anywhere else. Note that in `default/apps.cfg` we used `"default/myapp.cfg"` and not `"myapp.cfg"`. This is because the server looks for configuration files starting in `server/config`. Note also that the main configuration file of the EASYINTERFACE server is `server/config/eiserver.default.cfg`, and that `default/apps.cfg` is imported into that file (open `server/config/eiserver.default.cfg` to see this).

Let us test our application. Go back to the web-client and reload the page, you should see a new application named MFA in the applications menu. If you click on the `Help` button you will see the text provided inside the `apphelp` tag above. Select this application and click on the `Apply` button, the message "Hello World!" will be printed in the console area.

2.2 Passing Input Files to Your Application

Applications typically receive input files (e.g., programs) to process. You must have noticed that the web-client provides the possibility of creating and editing such files. In this section we explain how to pass these files, via the server, to our application when the **Apply** button is clicked.

When you click on the **Apply** button the web-client passes the currently opened file (i.e., the content of the active tab) to the server, and if you use the **Apply** option from the context menu of the file-manager (select an element from the files tree on the left, and use the mouse right-click to open the context menu) it passes all files in the corresponding sub-tree. What is left is to tell the server how to pass these files to our application. Let us assume that `myapp.sh` is prepared to receive input files as follows:

```
> myapp.sh -f file1.c file2.c file3.c
```

In order to tell the server to pass the input files (that were received from the client) to `myapp.sh`, open `myapp.cfg` and change the command-line template to the following:

```
<cmdlineapp>./bin/default/myapp.sh -f _ei_files</cmdlineapp>
```

When the server receives the files from the client, it stores them in a temporary directory, e.g., in `/tmp`, replaces `_ei_files` by the list of their names, and then execute the resulting command-line (now you see why we call it command-line template). It is important to note that only `_ei_files` changes in the above template, the rest remain the same. Thus, the parameter `-f` means nothing to the server, we could replace it by anything else or even completely remove it — that depends only on how our application is programmed to receive input files.

Let us now change `myapp.sh` to process the received files in some way, .e.g., to print the number of lines in each file. For this, replace the content of `myapp.sh` by the following:

```
1 #!/bin/bash
2
3 . default/parse_params.sh
4
5 echo "I've received the following command-line parameters:"
6 echo ""
7 echo "  $@"
8
9 echo ""
10 echo "File statistics:"
11 echo ""
12 for f in $files
13 do
14     echo "  - $f has " `wc -l $f | awk '{print $1}'` "lines"
15 done
```

Let us explain the above code. At line 3 we executes an external bash-script to parse the command-line parameters, the details are not important and all you should know is that it leaves the list of files (that appear after `-f`) in the variable `files`. Lines 5-7 print the command-line parameters, just to give you an idea how the server called `myapp.sh`, and the loop at lines 12-15 traverses the list of files and prints the number of lines in each one.

Let us test our application. First run `myapp.sh` from a shell passing it some existing text files, just to check that it works correctly. Then go back to the web-client, reload the page, select MFA from the applications menu, open a file from the file-manager, and finally click the **Apply** button. Alternatively, you can also select an entry from the file-manager and choose **Apply** from its context menu. You should see the output of the application in the console area.

2.3 Passing Outline Entities to Your Application

In the web-client, the area on the right is called the outline area (see Figure ??). Since EASYINTERFACE was designed mainly for applications that process programs, e.g., program analysis tools, this area is typically dedicated for a tree-view of program entities, e.g., method names, class names, etc. The idea is that, in addition to the input files, the user will select some of these entities to indicate, for example, where the analysis should start from or which parts of the program to analyze. Next we explain how we can pass these selected entities to an application.

By default the web-client is configured to work with C programs, and thus if you open such a program (from the file-manager) and then click on the **Refresh Outline** button, you will get a tree-view of this program entities, e.g., method names (if you use **Refresh Outline** from the context menu in the file-manager you will get a tree-view of program entities for all files in the sub-tree). Note that to generate this tree-view the web-client actually executes a “hidden” application that is installed on the server, namely `server/bin/default/coutline.sh`, but this is not relevant to our discussion now (see Section ?? for more details). Note also that `coutline.sh` is limited and will not work perfectly for any C program: it simply looks for lines that start with `int` or `void` followed by something of the form `name(...)`. This script is provided just to give an idea on how an application that generates an outline is connected to the web-client (see Section ?? for more details).

As in the case of input files, the web-client always passes the selected entities to the server when the **Apply** button is clicked, and it is our responsibility to indicate how these entities should be passed to our application. Let us assume that `myapp.sh` is prepared to receive entities using a “-e” parameter as follows:

```
> myapp.sh -f file1.abs file2.abs file3.abs -e sum.c:main sum.c:sum
```

In order to tell the server to pass the entities (that were received from the client) to our application, open `myapp.cfg` and change the command-line template to the following:

```
<cmdlineapp>./bin/myapp.sh -f _ei_files -e _ei_outline </cmdlineapp>
```

As in the case of files, before executing the above command-line the server will replace `_ei_outline` by the list of received entities. Let us now change `myapp.sh` to process these entities in some way, e.g., printing them on the standard output. Open `myapp.sh` and add the following lines at the end:

```
1 echo ""
2 echo "Selected entities:"
3 echo ""
4 for e in $entities
5 do
6     echo "- $e"
7 done
```

This code simply print the entities in separated lines. Again, the external script `parse_params.sh` parses the command-line and stores the list of entities in the variable `entities`.

Go back to the web-client, reload the page, select some files and entities and execute the MFA application to see the result of the last changes. It is always recommended to check that the application works correctly from a shell first.

2.4 Passing Parameters to Your Application

In addition to input files and outline entities, real applications receive other parameters to control different aspects. In this section we explain how to declare parameters in the EASYINTERFACE framework such that (1) they automatically appear in the web-client (or any other client) so the user can set their values; and (2) the selected values are passed to the application when executed.

Let us start by modifying `myapp.sh` to accept some command-line parameters: we add a parameter “-s” to indicate if the received outline entities should be printed; and “-c W” that takes a value W to indicate what to count in each file — here W can be “lines”, “words” or “chars”. For example, `myapp.sh` could then be invoked as follows:

```
> myapp.sh -f file1.abs file2.abs file3.abs -e sum.c:main sum.c:sum -s -c words
```

To support these parameters, change the content of `myapp.sh` to the following:

```
1 #!/bin/bash
2
3 . default/parse_params.sh
4
5 echo "I've received the following command-line parameters:"
6 echo ""
7 echo "  $@"
8
9 echo ""
10 echo "File statistics:"
11 echo ""
12
13 case $whattocount in
14     lines) wcpam="-l"
15     ;;
16     words) wcpam="-w"
17     ;;
18     chars) wcpam="-m"
19     ;;
20 esac
21
22 for f in $files
23 do
24     echo " - $f has " `wc $wcpam $f | awk '{print $1}` $whattocount
25 done
26
27 if [ $showoutline == 1 ]; then
28     echo ""
29     echo "Selected entities:"
30     echo ""
31     for e in $entities
32     do
33         echo "- $e"
34     done
35 fi
```

Compared to the previous script, you can notice that: we added lines 13-20 to take the value of “-c” into account when calling `wc` at line 24; and in lines 27-35 we wrapped the loop that prints the outline entities with a condition. Note that `parse_params.sh` sets the variable `whattocount` to the value of “-c”, and sets `showoutline` to 1 if “-s” is provided in the command-line and to 0 otherwise. Before proceeding to the next step, execute the script from a shell to make sure that it works correctly.

Our goal is show these parameters in the web-client (or any other client), so the user can select the appropriate values before executing the application. The `EASYINTERFACE` framework provides an easy way to do this, all we have to do is to modify `myapp.cfg` to include a description of the supported parameters. Open `myapp.cfg` and add the following inside the `app` tag (e.g., immediately after `execinfo`):

```
<parameters prefix = "-" check="false">
  <selectone name="c">
    <desc>
```

```

    <short>What to count</short>
    <long>Select the elements you want to count in each input file</long>
</desc>
<option value="lines">
    <desc>
        <short>Lines</short>
        <long>Count lines</long>
    </desc>
</option>
<option value="words">
    <desc>
        <short>Words</short>
        <long>Count words</long>
    </desc>
</option>
<option value="chars" >
    <desc>
        <short>Chars</short>
        <long>Count characters</long>
    </desc>
</option>
<default value="lines"/>
</selectone>
<flag name="s">
    <desc>
        <short>Show outline</short>
        <long>Show the selected outline entities</long>
    </desc>
    <default value="false"/>
</flag>
</parameters>

```

Let us explain the different elements of the above XML snippet. The tag `parameters` includes the definition of all parameters. The attribute `prefix` is used to specify the symbol to be attached to the parameter name when passed to the application, for example, if we declare a parameter with name "c" the server will pass it to the application as "-c". Note that this attribute can be overridden by each parameter. The attribute `check` tells the server to check the correctness of the parameters before passing them to the application, i.e., that they are valid values, etc. The tag `selectone` defines a parameter with name "c" that can take one value from a set of possible ones. For example, the web-client will view it as a ComboBox. The `desc` environment contains a text describing this parameter and is used by the client when viewing this parameter graphically. The `option` tags define the valid values for this parameter, from which one can be selected, and the `default` tag defines the default value. The `desc` environment of each `option` contains a text describing this option, e.g., the `short` description is used for the text in the corresponding ComboBox. The tag `flag` defines a parameter with name "s". This parameter has no value, it is either provided in the command-line or not, and its `default` value is "false", i.e., not provided. For the complete set of parameters supported in EASYINTERFACE see [PARAMETERS] in Chapter ??.

Go to the web-client, reload the page, and click on the `Settings` button and look for the tab with the title MFA. You will now see the parameters declared above in a graphical way where you can set their values as well. When you click on the `Apply` button, the web-client will pass these parameters to the server, however, we still have to tell the server how to pass these parameters to `myapp.sh`. Open `myapp.cfg` and change the `cmdlineapp` template to the following:

```
<cmdlineapp>./bin/myapp.sh -f _ei_files -e _ei_outline _ei_parameters </cmdlineapp>
```

As in the case of `_ei_files` and `_ei_outline`, the server will replace `_ei_parameters` by the list of received parameters before executing the command-line. Execute the MFA application from the web-client with different values for the parameters to see how the output changes.

2.5 Using the EASYINTERFACE Output Language in Your Application

In the example that we have developed so far, the web-client simply printed the output of `myapp.sh` in the console area. This is the default behavior of the web-client if the output does not follow the EASYINTERFACE Output Language (EIOL), which is a text-based language that allows generating more sophisticated output such as highlighting lines, adding markers, etc. In this section we will explain the basics of this language by extending `myapp.sh` to use it, for more details see Chapter ??.

An output in EIOL is an XML structure of the following form:

```
<eiout>
  <eicommands>
    [EICOMMAND]*
  </eicommands>
  <eiactions>
    [EIACTION]*
  </eiactions>
</eiout>
```

where (1) `eiout` is the outermost tag that includes all the output elements; (2) `[EICOMMAND]*` is a list of commands to be executed; and (3) `[EIACTION]*` is a list of actions to be declared. An `[EICOMMAND]` is an instruction like: *print a text on the console, highlight lines 5-10, add marker at line 5*, etc. An `[EIACTION]` is an instructions like: *when the user clicks on line 13, highlight lines 20-25*, etc. In the rest of this section we discuss some commands and actions that are supported in EIOL, for the complete list see Chapter 5.

2.5.1 Printing in the Console Area

Recall that when the EIOL is used, the web-client does not redirect the output to the console and thus we need a command to print in the console area. The following is an example of a command that prints “Hello World” in the console area:

```
<printonconsole consoleid="1" consoletitle="Welcome">
  <content format="text">
    Hello World
  </content>
</printonconsole>
```

The value of the `consoleid` attribute is the console identifier in which the given text should be printed (e.g., in the web-client the console area has several tabs, so the identifier refers to one of those tabs). If a console with such identifier does not exist yet, a new one, with a title as specified in `consoletitle`, is created. If `consoleid` is not given the output goes to the default console. Inside `printonconsole` we can have several `content` tags which include the content to be printed (in the above example we have only one). The attribute `format` indicates the format of the content. In the above example it is plain ‘text’, other formats are supported as well, e.g., ‘html’.

Let us change `myapp.sh` to print the different parts of its output in several consoles. Open `myapp.sh` and change its content to the following:

```
1 #!/bin/bash
2
3 . default/parse_params.sh
4
5 echo "<eiout>"
6 echo "<eicommands>"
7 echo "<printonconsole>"
8 echo "<content format='text'>"
9 echo "I've received the following command-line parameters:"
10 echo ""
11 echo "    $@"
```

```

12 echo "</content>"
13 echo "</printonconsole>"
14
15 echo "<printonconsole consoleid='stats' consoletitle='Statistics'>"
16 echo "<content format='html'>"
17 echo "File statistics:"
18 echo "<div>"
19 echo "<ul>"
20
21 case $whattocount in
22     lines) wcpam="-l"
23     ;;
24     words) wcpam="-w"
25     ;;
26     chars) wcpam="-m"
27     ;;
28 esac
29
30 for f in $files
31 do
32     echo " <li> $f has " `wc $wcpam $f | awk '{print $1}'` $whattocount "</li>"
33 done
34 echo "</ul>"
35 echo "</div>"
36 echo "</content>"
37 echo "</printonconsole>"
38
39 if [ $showoutline == 1 ]; then
40     echo "<printonconsole consoleid='outline' consoletitle='Outline'>"
41     echo "<content format='html'>"
42     echo ""
43     echo "Selected entities:"
44     echo "<ul>"
45     echo ""
46     for e in $entities
47     do
48         echo "<li> $e </li>"
49     done
50     echo "</ul>"
51     echo "</content>"
52     echo "</printonconsole>"
53 fi
54 echo "</eicommands>"
55 echo "</eiout>"

```

The output of `myapp.sh` is given in EIOL, because at Line 5 we start the output with the tag `eiout` which we close at line 55. At Line 6 we start an `eicommands` tag, inside `eiout`, which we close at Line 54. Inside `eicommands` we have 3 `printonconsole` commands: the first one is generated by lines 7-13; the second by lines 15-37; and the last one by lines 40-52. Note that the first command uses the default console, while the last two use different consoles. Note also that the content in the last two is given in HTML. Execute `myapp.sh` in a shell first to check that it works correctly, and then execute the MFA application from the web-client to see the effect of these changes.

2.5.2 Adding Markers

Next we explain a command for adding a marker next to a code line in the editor area. The following is an example of such command:

```
<addmarker dest="path" outclass="info">
```

```

<lines>
  <line from="4" />
</lines>
<content format='text'>
  text to associated to the marker
</content>
</addmarker>

```

The attribute **dest** indicates the *full path* of the file in which the marker should be added. The attribute **outclass** indicates the nature of the marker, which can be 'info', 'error', or 'warning'. This value typically affects the type/color of the icon to be used for the marker. The tag **lines** includes the lines in which markers should be added, each line is give using the tag **line** where the **from** attribute is the line number (**line** can be used to define a region in other commands, this is why the attribute is called **from**). The text inside the **content** tag is associated to the marker (as a tooltip, a dialog box, etc., depending on the client).

Let us modify `myapp.sh` to add a marker at Line 1 of each file that it receives. Open `myapp.sh` and add the following code snippet immediately before 54 of the previous script (i.e., immediately before closing the **ecommands** tag):

```

1 for f in $files
2 do
3   echo "<addmarker dest='$f' outclass='info'>"
4   echo "<lines><line from='1' /></lines>"
5   echo "<content format='text'> text for info marker of $f</content>"
6   echo "</addmarker>"
7 done

```

Lines 3-6 generate the actual command to add a marker for each file passed to `myapp.sh`. Execute `myapp.sh` in a shell first to check that it works correctly, and then execute the MFA application from the web-client to see the effect of these changes.

2.5.3 Highlighting Code Lines

The following command can be used to highlight code lines:

```

<highlightlines dest="path" outclass="info" >
  <lines>
    <line from="5" to="10"/>
  </lines>
</highlightlines>

```

Attributes **dest** and **outclass** are as in the **addmarker** command. Each **line** tag define a region to be highlighted. E.g., in the above example it highlights lines 5-10. You can also use the attributes **fromch** and **toch** to indicate the columns in which the highlight starts and ends respectively.

Let us modify `myapp.sh` to highlight lines 5-10 of each file that it receives. Open `myapp.sh` and add the following code snippet immediately before the instruction that closes the **ecommands** tag:

```

1 for f in $files
2 do
3   echo "<highlightlines dest='$f' outclass='info'>"
4   echo "<lines><line from='5' to='10' /></lines>"
5   echo "</highlightlines>"
6 done

```

Execute `myapp.sh` in a shell first to check that it works correctly, and then execute the MFA application from the web-client to see the effect of these changes.

2.5.4 Adding Inline Markers

Inline markers are widgets placed inside the code. They typically include some read-only text. The following command adds an inline marker:

```
<addinlinemarker dest="path" outclass="info">
  <lines><line from="15" /></lines>
  <content format="text">
    Text to be viewed in the inline marker
  </content>
</addinlinemarker>
```

Attributes **dest** and **outclass** are as in the **addmarker** command. Each **line** tag defines a line in which a widget, showing the text inside the **content**, is added. Note that some client, e.g., the web-client, allow only plain 'text' content.

Let us modify `myapp.sh` to add an inline marker at line 15 of each file that it receives. Open `myapp.sh` and add the following code snippet immediately before the instruction that closes the **ecommands** tag:

```
1 do
2   echo "<addinlinemarker dest='$f' outclass='info'>"
3   echo "  <lines><line from='15' /></lines>"
4   echo "  <content format='text'> Awesome line of code!!</content>"
5   echo "</addinlinemarker>"
6 done
```

Execute `myapp.sh` in a shell first to check that it works correctly, and then execute the MFA application from the web-client to see the effect of these changes.

2.5.5 Opening a Dialog Box

The following command can be used to open a dialog box with some content:

```
<dialogbox outclass="info" boxtitle="Done!" boxwidth="100" boxheight="100">
  <content format="html">
    text to be shown in the dialog box
  </content>
</dialogbox>
```

The dialog box will be titled as specified in **boxtitle**, and it will include the content as specified in the **content** environments. The attributes **boxwidth** and **boxheight** are optional, they determine the initial size of the window.

Let us modify `myapp.sh` to open a dialog box with some message. Open `myapp.sh` and add the following code snippet immediately before the instruction that closes the **ecommands** tag:

```
1 echo "<dialogbox outclass='info' boxtitle='Done!' boxwidth='300' boxheight='100'>"
2 echo "  <content format='html'>"
3 echo "    The <span style='color: red'>MFA</span> analysis has been applied."
4 echo "    You can see the output in the result in the text area and the corresponding"
5 echo "    program files."
6 echo "  </content>"
7 echo "</dialogbox>"
```

Execute `myapp.sh` in a shell first to check that it works correctly, and then execute the MFA application from the web-client to see the effect of these changes.

2.5.6 Adding Code Line Actions

A *code line action* defines a list of commands to be executed when the user clicks on a line of code (more precisely, on a marker placed next to the line). The commands can be any of those seen above. The following is an example of such action:

```
<oncodelineclick dest="/Examples_1/iterative/sum.c" outclass="info" >
  <lines><line from="17" /></lines>
  <ecommands>
    <highlightlines>
      <lines>
        <line from="17" to="19"/>
      </lines>
    </highlightlines>
    <dialogbox boxtitle="Hey!">
      <content format="html">
        Click on the marker again to close this window
      </content>
    </dialogbox>
  </ecommands>
</oncodelineclick>
```

First note that the above XML should be placed inside the `eiactions` tag (that we have ignored so far). When the above action is executed, by the web-client for example, a marker (typically an arrow) will be shown next to line 17 of the file `/Examples_1/iterative/sum.c`. Then, if the user clicks on this marker the commands inside the `ecommands` tag will be executed, and if the user clicks again the effect of these commands is undone. In the above case a click highlights lines 17-19 and opens a dialog box, and another click removes the highlights and closes the dialog box. Note that the commands inside `ecommands` inherit the `dest` and `outclass` attributes of `oncodelineclick`, but one can override them, e.g., if we add `dest="/Examples_1/iterative/fact.c"` to the `highlightlines` command then a click highlights lines 17-19 of `fact.c` instead of `sum.c`.

Let us modify `myapp.sh` to open add a code line action, as the one above, for each file that it receives. Open `myapp.sh` and add the following code snippet immediately before the instruction that closes the `eiout` tag (i.e., after closing `ecommands`):

```
1 echo "<eiactions>"
2
3 for f in $files
4 do
5   echo "<oncodelineclick dest='$f' outclass='info' >"
6   echo "<lines><line from='17' /></lines>"
7   echo "<ecommands>"
8   echo "<highlightlines>"
9   echo "<lines><line from='17' to='19' /></lines>"
10  echo "</highlightlines>"
11  echo "<dialogbox boxtitle='Hey!'> "
12  echo "<content format='html'>"
13  echo "Click on the marker again to close this window"
14  echo "</content>"
15  echo "</dialogbox>"
16  echo "</ecommands>"
17  echo "</oncodelineclick>"
18 done
19
20 echo "</eiactions>"
```

Note that at line 1 we open the tag `eiactions` and at line 21 we close it. The rest of the code simply prints a code line action as the one above for each file. Execute `myapp.sh` in a shell first to check that it works correctly, and then execute the MFA application from the web-client to see the effect of these changes.

2.5.7 Adding OnClick Actions

OnClick actions are similar to code line actions. The difference is that instead of assigning the action to a line of code, we can assign it to any HTML tag that we have generated. For example, suppose that at some point the application has generated the following content in the console area:

```
<content format="html"/>
  <span style="color: red;" id="err1">10 errors</span> were found in the file sum.c
</content>
```

Note that the text “10 errors” is wrapped by a span tag with an identifier err1. The OnClick action can assign a list of commands to be executed when this text is clicked as follows:

```
<onclick>
  <elements>
    <selector value="#err1"/>
  </elements>
  <ecommands>
    <dialogbox boxtitle="Errors">
      <content format="html">
        There are some variables used but not declared
      </content>
    </dialogbox>
  </ecommands>
</onclick>
```

It is easy to see that this action is very similar to `oncodeclick`, the difference is that instead of `lines` we now use `elements` to identify those HTML elements a click on which should execute the commands.

Let us modify `myapp.sh` to open and add an OnClick action assigned to the list of files that it prints on the console. First look for the first occurrence of

```
1 echo "<ul>"
```

which should be at line 19, and change it by

```
1 echo "<ul style='background: yellow;' id='files'>"
```

This change will give the list of files that we print in the console the identifier `files`, and will change its background color to yellow. Next add the following code immediately before the instruction that closes `eiactions`:

```
1 echo "<onclick>"
2 echo "<elements>"
3 echo "<selector value='#files'/"
4 echo "</elements>"
5 echo "<ecommands>"
6 echo "<dialogbox boxtitle='Errors'> "
7 echo "<content format='html'>"
8 echo "There are some variables used but not declared"
9 echo "</content>"
10 echo "</dialogbox>"
11 echo "</ecommands>"
12 echo "</onclick>"
```

Execute `myapp.sh` in a shell first to check that it works correctly, and then execute the MFA application from the web-client to see the effect of these changes. In particular, clicking on the list of files in the console area (anywhere in the yellow region) should open a dialog box.

3 | Easy Interface Server

This chapter describes the server side of the EASYINTERFACE platform. In particular how to install it on an HTTP server and set some parameters, how to make applications (APPS) available, and how to make examples available.

3.1 Installing the Server

All you need to make the directory **server** accessible through the HTTP server, and moreover PHP access must be guaranteed to this directory.

3.2 Configuring the Applications Server

The applications server requires a configuration file that defines some setting parameters, available applications, and available examples. By default, it uses dowithconfig/eiserver.cfg, however, this can be changed by editing the dowithserver/EIConfig.php. The content of this file should adhere to the **EISERVER** XML structure as described in Section 3.3

3.3 Configuration XML Reference

EISERVER

```
<eiserver>
  [SETTINGS]?
  [EXAMPLES]?
  [APPS]?
</eiserver>
```

DESCRIPTION:

This XML tag should be the root of the configurations file (see Section 3.2). The **[SETTINGS]** section is used for setting some global parameters; the **[APPS]** section defines which APPs are available on the server; and **[EXAMPLES]** defines which example groups are available on the server.

USED IN: The server configuration file (see Section 3.2)

SETTINGS

```
<settings>
</settings>
```

DESCRIPTION:

To be done, so far we do not have any global parameter

USED IN: **EISERVER**

EXAMPLES

```
<examples>
  [EXSET]*
</examples>
```

DESCRIPTION:

Example groups available on the server

USED IN: EISERVER

EXSET

```
<exset id=[EXAMPLEID]>
  [EXELEMENTS]*
</exset>
```

DESCRIPTION:

The **id**
Contains diferents types of elements

USED IN: EXAMPLES

EXELEMENTS

```
(
  [FOLDER]
| [FILE]
| [GITHUB]
)
```

DESCRIPTION:

Diferent types of element

USED IN: EXSET, FOLDER

FOLDER

```
<folder name=[NAME]? internal=[NAME]>
  [EXELEMENTS]*
</folder>
```

internal not implemented yet

DESCRIPTION:

Default values:
name -> internal

USED IN: EXELEMENTS

FILE

```
<file name=[NAME]? internal=[NAME] url=[URL] />
```

```
internal not implemented yet
```

DESCRIPTION:

Default values:
name -> internal

USED IN: EXELEMENTS

GITHUB

```
<github name=[NAME]? internal=[NAME]? owner=[NAME] repo=[NAME]  
branch=[NAME]? path=[PATH]? />
```

```
internal not implemented yet
```

DESCRIPTION:

Default values:
branch -> "master"
path -> "/"
internal -> "owner + @ + repo"
name -> internal

USED IN: EXELEMENTS

APPS

```
<apps>  
  [APP]*  
</apps>
```

DESCRIPTION:

Defines a list of APPs (to be available on the EASYINTERFACE server). Each APP is defined by an APP XML structure.

USED IN: EISERVER

APP

```
<app id=[APPID] visible=[BOOL]? >  
  [APPINFO]  
  [APPHELP]?  
  [EXECINFO]  
  [PARAMETERS]?  
  [PERMISSION]?  
</app>
```

OR

```
<app id=[APPID] src=[FILENAME] />
```

DESCRIPTION:

Defines an app, where the different parts are as follows:

- **id** is an identifier used when referring to the APP, it should be unique among the APPs available on the same server.
- **visible** indicates if the APP should be listed when the list of available APPs is requested, by default it is **true**. Note that even if an app is not *publicly* visible, it can be used like any other APP (you just need to know its identifier).
- **[APPINFO]** provides some general information about the APP, like title, logo, description, etc.
- **[APPHELP]** is a (formatted) text that provides enough information on how the APP can be used, etc. It will be mainly used in the help sections of the different clients.
- **[EXECINFO]** defines how the tool can be executed (e.g., command-line, server). This information is used by the APPs server to forward execution requests to corresponding APPs.
- **[PARAMETERS]** defines the parameters accepted by the APP. This parameters are usually passed to client, who will allow users to select the appropriate values, and when an execution request is sent to the APPs server, these options are passed to the corresponding APP.
- **[PERMISSION]** defines some usage permissions for the APP, e.g., who have permission to execute this app. By default any one can execute.

USED IN: APPS

APPINFO

```
<appinfo>
  [ACRONYM]?
  [TITLE]?
  [LOGO]?
  [DESC]?
</appinfo>
```

DESCRIPTION:

Provides general information on an app:

- **[ACRONYM]** is an acronym for the app, e.g., COSTA;
- **[TITLE]** is a title for the app ;
- **[LOGO]** is an image to be used as the app's logo; and
- **[DESC]** is a (general) description of the tool.

USED IN: APP

ACRONYM

```
<acronym>[TEXT]</acronym>
```

DESCRIPTION:

Plain text to be used as an acronym, e.g., COSTA.

USED IN: **APPINFO**

TITLE

```
<title>[TEXT]</title>
```

DESCRIPTION:

Plain text deciding a title. Typically more informative than an acronym (see **[ACRONYM]**).

USED IN: **APPINFO**

LOGO

```
<logo src=[URL] />
```

DESCRIPTION:

A link to an image — in some standard format such **png**, **jpg** or **gif** — to be used by clients as a logo (for an APP). The size of the image typically has equal height and width (but this is not a requirement).

USED IN: **APPINFO**

DESC

```
<desc>
  <short>[TEXT]</short>
  <long>[TEXT]</long>
</desc>
```

DESCRIPTION:

This is a description of some entities, e.g., of an APP, a parameter, a parameter option, etc. It consists of two parts, the first one is a short description, and the second is a detailed description. In both cases it should be plain text. Clients will select one of them depending on the intended use. The description is typically high-level.

USED IN: **APPINFO, SELECTONE, SELECTMANY**

APPHELP

```
<apphelp>
  [CONTENT]+
</apphelp>
```

DESCRIPTION:

A (formatted) text that provides enough information on how an APP can be used, etc. It can be provided in several formats, e.g., html or plain text, by using several **[CONTENT]** tags. Client are supposed to pick the appropriate format. It is recommended to always include a content in plain text since it can be view in any client.

USED IN: APP

CONTENT

```
<content format=[TEXTFORMAT]? >
  [TEXT]
</content>
```

DESCRIPTION:

A text given in a specific **format**, e.g., "text", "html", etc. If the attribute **format** is not provided, then it is assumed to be "text" format (plain text).

USED IN: APPHELP, EICOMMAND

EXECINFO

```
<execinfo>
  ( [CMDLINEAPP] | [SERVERAPP] )
</execinfo>
```

DESCRIPTION:

Provides information on how to execute an app. It can be either a command-line app [CMDLINEAPP], or a server based app [SERVERAPP].

USED IN: APP

CMDLINEAPP

```
<cmdlineapp> [COMMAND_TEMPLATE] </cmdlineapp>
```

DESCRIPTION:

Describes how to run a command-line APP, where **COMMAND_TEMPLATE** is a template describing a command-line. It is best explained by an example. Consider the following template example

```
/path-to/app _ei_files -m _ei_outline _ei_parametes
```

In this template, anything that starts with **_ei** is a template parameter that will be replaced by some corresponding information, and /path-to/app is the APP's executable. When the server receives a request for executing the corresponding APP, the request includes several data that should be passed to the APP. For example, the following are typical data that should be passed to an APP is:

1. files to be processed (e.g., program to be analysed);
2. entities selected from the program outline (e.g., methods); and
3. values for the different parameters.

The server passes this data to the APP by replacing the template parameters with corresponding data as follows:

1. the files are stored locally (e.g., in /tmp), and **_ei_files** is replaced by a list file names (each with an absolute path, separated by a space);
2. **_ei_outline** is replaced by a list of selected entities (e.g., method names) — see TODO; and

3. `_ei_parametes` is replaced by the list of parameters generated from those provided in the request (see TODO).

This result in, for example, the following instance of the template:

```
/path-to/app a.java b.java -m a.main -v 1 -d 3 -a
```

which is then executed and its output is redirected to the client. The server does some security checks to guarantee that the command-line is not executed in a bad way (see Section ??)

The following is a list of template parameters:

- `_ei_files` which is replaced by a list of file names (separated by space) in the local file system;
- `_ei_dirs` which is replaced by a list of dirs in the local file system;
- `_ei_root` which is replaced by the local temporary directory name, where all files have been saved;
- `_ei_outline` which is replaced by a list of selected entities (separated by space);
- `_ei_parametes` which is replace by a corresponding list of parameters — see Section ?? for information on how this list is constructed;
- `_ei_sessionid` which is replaced by a session identifier, this makes it possible to track the information of a user along several request (see Section ??)
- `_ei_clientid` which is replaced by a the client identifier, i.e., web-interface, eclipse, etc, which makes it possible to provide output depending on the client (not recommended since it double the amount of work). See Section ?? for a list of clients.

USED IN: **EXECINFO**

SERVERAPP

```
<serverapp url=[URL] />
```

DESCRIPTION:

Defines a server based application that is available at the address specified by the attribute `url`. In this kind of apps the APPs server passes the request, as it is, to the app — See Section ?? for more information.

USED IN: **EXECINFO**

PARAMETERS

```
<parameters prefix=[PARAMPREFIX]? check=[BOOL]?>
  [PARAM]*
</parameters>
```

DESCRIPTION:

Defines a list of parameters that are accepted by a corresponding tool. In the `prefix` attribute you can specify a string that will be attached to each parameter name when passed to the app (only in command-line mode, see **CMDLINEAPP**). For example, if `prefix="--"` and we have a parameter called 'level' with value X, then '--level X' will be passed to the app. The default value of `prefix` is `"-"`. You can set `prefix` to the empty string `""` if there is no need to attach anything to the option name, in such case the parameter name will probably include this prefix as part of its name. Also, you can indicate in

the **check** attribute if you want or not that the parameters be check with your specification. The default value of **check** is **"true"**. **check** value is like the **prefix** value, it is inherit on all parameters, but you can change on each one this properties.

USED IN: **APPINFO**

PARAM

```
(
  [SELECTONE]
|  [SELECTMANY]
|  [FLAG]
|  [TEXTFIELD]
|  [HIDDEN]
)
```

DESCRIPTION:

Defines a parameter accepted by a corresponding app. There are several types of paramaters supported

USED IN: **PARAMETERS**

SELECTONE

```
<selectone name=[PARAMNAME]
  prefix=[PARAMPREFIX]? check=[BOOL]? widgetid=[WIDGETID]? >
  [DESC]
  [OPTION]+
  [DEFAULTVALUE]?
</selectone>
```

DESCRIPTION:

Defines a parameter that takes a *single* value out of a given list:

- **name** is the name of the parameter, it must be unique among all parameters of an app;
- **[DESC]** describes the meaning of the parameter;
- **[PARAMVALUE]**+ is a list of possible values for this parameter;
- **[DEFAULTVALUE]** specifies the default value. If not specified then the first **[PARAMVALUE]** is considered as the default one;
- **widgetid** specifies the preferred layout when used in a client with a graphical interface (e.g., combo-box, radio button, etc.). See **[WIDGETID]** for a list of widgets for this kind of parameter.
- **prefix** and **check** can override the default value of these attributes, specified in **[PARAMETERS]**, for this particular parameter.

USED IN: **PARAM**

SELECTMANY

```
<selectmany name=[PARAMNAME]
  prefix=[PARAMPREFIX]? check=[BOOL]? widgetid=[WIDGETID]? >
  [DESC]
  [OPTION]+
```

```
[DEFAULTVALUE]*
</selectmany>
```

DESCRIPTION:

Defines a parameter that takes *several* values out of a given list:

- **name** is the name of the parameter, it must be unique among all parameters of an app;
- **[DESC]** describes the meaning of the parameter;
- **[PARAMVALUE]+** is a list of possible values for this parameter;
- **[DEFAULTVALUE]** specifies the default value. If not specified then the first **[PARAMVALUE]** is considered as the default one;
- **widgetid** specifies the preferred layout when used in a client with a graphical interface (e.g., combo-box, radio button, etc.). See **[WIDGETID]** for a list of widgets for this kind of parameter.
- **prefix** and **check** can override the default value of these attributes, specified in **[PARAMETERS]**, for this particular parameter.

USED IN: **PARAM**

FLAG

```
<flag name=[PARAMNAME]
  prefix=[PARAMPREFIX]? check=[BOOL]? widgetid=[WIDGETID]? >
  [DESC]
  [DEFAULTVALUE]?
</flag>
```

DESCRIPTION:

In this case the default should specify just *true* or *false*. This is ONLY to say if one parameter appears or not.

- **name** is the name of the parameter, it must be unique among all parameters of an app;
- **[DESC]** describes the meaning of the parameter;
- **[DEFAULTVALUE]** specifies the default value. If not specified then the *false* value is considered as the default one;
- **widgetid** specifies the preferred layout when used in a client with a graphical interface (e.g., combo-box, radio button, etc.). See **[WIDGETID]** for a list of widgets for this kind of parameter.
- **prefix** and **check** can override the default value of these attributes, specified in **[PARAMETERS]**, for this particular parameter.

USED IN: **PARAM**

TEXTFIELD

```
<textfield name=[PARAMNAME]
  prefix=[PARAMPREFIX]? check=[BOOL]? widget=[WIDGETID]? >
  [DESC]
  [DEFAULTVALUE]?
</textfield>
```

DESCRIPTION:

In this case the parameter is some text, this text will be passed to the app as a string or file depending on the flag **method**

- **name** is the name of the parameter, it must be unique among all parameters of an app;
- **[DESC]** describes the meaning of the parameter;
- **[DEFAULTVALUE]** specifies the default value.
- **widgetid** specifies the preferred layout when used in a client with a graphical interface (e.g., combo-box, radio button, etc.). See **[WIDGETID]** for a list of widgets for this kind of parameter.
- **prefix** and **check** can override the default value of these attributes, specified in **[PARAMETERS]**, for this particular parameter.

USED IN: **PARAM**

HIDDEN

```
<hidden name=[PARAMNAME]
  prefix=[PARAMPREFIX]?
  value=[PARAMVALUE]? />
```

DESCRIPTION:

In this case the parameter is not showed in the app but the value is used like an other parameter.

- **name** is the name of the parameter, it must be unique among all parameters of an app;
- **value** specifies the value.
- **prefix** can override the default value of this attribute, specified in **[PARAMETERS]**, for this particular parameter.

USED IN: **PARAM**

PERMISSION

```
<permission default=[BOOL]>
  [ALLOWED]*
  [EXCLUDED]*
</permission>
```

DESCRIPTION:

This is a list of users that are allowed or excluded to execute an app. **default** is the default value to all user that doesn't appear on this list. If an user appear in both list, the list of excluded is the most important.

USED IN: **APP**

ALLOWED

```
<allowed>
  [USER]*
</allowed>
```

DESCRIPTION:

This is a list of users that are allowed to use an app.

USED IN: **PERMISSION**

EXCLUDED

```
<excluded>
  [USER]*
</excluded>
```

DESCRIPTION:

This is a list of users that are excluded to use an app.

USED IN: **PERMISSION**

USER

```
<user id=[USERID] />
```

DESCRIPTION:

It has an **id** of a user.

USED IN: **ALLOWED, EXCLUDED**

OPTION

```
<option value=[PARAMVALUE]>[DESC]</option>
```

DEFAULTVALUE

```
<default value=[PARAMVALUE] />
```

or

```
<default>[PARAMVALUE] </default>
```

TEXTFORMAT

("text" | "html" | "svg")

PARAMVALUE

To Be Define

PARAMNAME

[a-z,A-Z,0-9,-,_,+]

INT

An integer value

BOOL

("true" | "false")

4 | Outline App

4.1 Input

I don't know the Input

4.2 Output

The Outline App returns an XML with the outline tree.

OUTLINE

```
<category text=[NODENAME]
  value=[NODENAME] selectable=[BOOL]?
  icon=[PATH]?>
  [OUTLINE]*
</category>
```

DESCRIPTION:

Defines a list of points to be analysed.

- **text** is the name to be show.
- **value** is the internalname .
- **selectable** indicates if this node can be selected.
- **icon** indicates an alternative path for the icon of the node.

USED IN: **OUTLINE**

5 | The EASYINTERFACE Output Language

In this chapter we describe a text-based output language that allows application to view their output in a graphical way, e.g., highlighting lines, adding markers, defining on-click actions, etc. Some clients, e.g., the web-client, interpret this language and render the effect of the corresponding commands in the respective environment.

5.1 Brief description

5.2 Details XML output

EIOUT

```
<eiout version=[VERSION]? >
  [EICOMMANDS]*
  [EIACTIONS]*
</eiout>
```

DESCRIPTION:

This is the main environment of the output, it includes several list of commands environment [EICOMMANDS], and several list of actions actions [EIACTIONS]. Commands are executed first, in the given order, and then actions are executed in the given order as well. The **version** attribute indicates the version of the output language that is used, which is 1.0 by default.

USED IN: The APP response (see Section 5.1)

EICOMMANDS

```
<eicommands outclass=[OUTCLASS]? dest=[PATH]?>
  [EICOMMAND]*
</eicommands>
```

DESCRIPTION:

A list of commands to be performed. The attribute **dest** is the destination file on which the command is applied (if needed). E.g., when highlighting a line we might want to highlight a line in one file or another. If **dest** is not specified, then the commands will be applied to the file that is currently active, e.g., if the client have a code editor with several tabs, one for each file, the command will be applied to the active tab. If none is active then the behavior is not specified. The attribute **outclass** specifies the *output class* of the commands in this environment, that is, the nature of the corresponding output generated by the commands, e.g., error, information, warning, etc. All commands inside this environment inherit the values of **outclass** and **dest**, and each can overwrite them.

USED IN: EIOUT, ONCLICKACTION, ONCODELINECLICKACTION

EIACTIONS

```
<eactions dest=[PATH]? autoclean=[BOOL]?>
  [EIACTION]*
</eactions>
```

DESCRIPTION:

A list of actions to be declared. An action typically executes a list of [EICOMMANDS] when the user interacts with the interface in some predetermined way, e.g., *when the user clicks on line 30, highlight lines number 12 and 16*. We say the an action is *performed* as a response to the user interaction. If the user interacts again with the interface, according to what is specified in the action, then the action is *unperformed* if possible (when the corresponding commands support the *undo* operation), e.g., in the above example if the user clicks again on line 30 the highlights of lines 12 and 16 are turned off.

Before *performing* an action, the last *performed* action is *unperformed* first. This behavior can be disabled by setting the **autoclean** attribute to `false`'. All actions inside this environment inherit the value of **autoclean**, and each can overwrite it. The attribute **dest** and **outclass** are as in the case of commands (see the description of [EICOMMANDS]).

USED IN: EIOUT

EICOMMAND

```
(
  [PRINTONCONSOLECOMMAND]
| [HIGHLIGHTLINESCOMMAND]
| [DIALOGBOXCOMMAND]
| [WRITEFILECOMMAND]
| [SETCSSCOMMAND]
| [ADDMARKERCOMMAND]
| [ADDINLINEMARKERCOMMAND]
)
```

DESCRIPTION:

A command in the EASYINTERFACE output language, briefly:

- [PRINTONCONSOLECOMMAND] can be used to print on the console.
- [HIGHLIGHTLINESCOMMAND] can be used to highlight lines in the code editor.
- [DIALOGBOXCOMMAND] can be used to open a dialog window with a corresponding message.
- [WRITEFILECOMMAND] can be used to add a file (and a corresponding content) to the files tree.
- [SETCSSCOMMAND] can be used to change the CSS properties of some elements.
- [ADDMARKERCOMMAND] can be used to add a marker next to a line in the code editor.
- [ADDINLINEMARKERCOMMAND] can be used to add a line widget (an inlined marker) in the code editor.

USED IN: EICOMMANDS

EIACTION

```
(
  [ONCODELINECLICKACTION]
| [ONCLICKACTION]
)
```

DESCRIPTION:

An action in the EASYINTERFACE output language, briefly:

- **[ONCODELINECLICKACTION]** can be used to perform an action when the user clicks on a line in the code editor.
- **[ONCLICKACTION]** can be used to perform an action when the user clicks on a DOM element.

USED IN: **EIACTIONS**

PRINTONCONSOLECOMMAND

```
<printonconsole outclass=[OUTCLASS]? consoleid=[CONSOLEID]? consoletitle=[STR]?>
  [CONTENT]+
</printonconsole>
```

DESCRIPTION:

Print the content of the **[CONTENT]** environments on the console with identifier **consoleid**. If **consoleid** is not specified, the output goes to the default console. If **consoleid** is specified but there is no console with such an identifier, the console is created and **consoletitle** (if specified) is used as its title. The attribute **outclass** is as described in **[EICOMMANDS]**.

USED IN: **EICOMMAND**

HIGHLIGHTLINESCOMMAND

```
<highlightlines outclass=[OUTCLASS]? dest=[PATH]?>
  [LINES]*
</highlightlines>
```

DESCRIPTION:

Highlight the lines specified by **[LINES]** in the file **dest**. The attribute **outclass** is as described in **[EICOMMANDS]**.

USED IN: **EICOMMAND**

DIALOGBOXCOMMAND

```
<dialogbox outclass=[OUTCLASS]? boxtitle=[STR]? boxwidth=[INT]? boxheight=[INT]? >
  [CONTENT]+
</dialogbox>
```

DESCRIPTION:

Open a dialog box with the content specified by the **[CONTENT]** environments. The value of **boxtitle**, if specified, is used as a title for the dialog box. The attributes **boxwidth** and **boxheight** can be used to set the size of the window. The attribute **outclass** is as in **[EICOMMANDS]**.

USED IN: **EICOMMAND**

WRITEFILECOMMAND

```
<writefile filename=[PATH] overwrite=[BOOLEAN]>
  [TEXT]
</writefile>
```

DESCRIPTION:

Create a new file and place it in the files view, using the path specified by **filename**. The file is initialized with the all text insider this tag. If the file exists, and **overwrite** is true the content is replaced otherwise a new file is created with a new name. The default value of **overwrite** is false. This command does not support *undo*.

USED IN: EICOMMAND

SETCSSCOMMAND

```
<setcss>
  [ELEMENTS]
  [CSSPROPERTIES]
</setcss>
```

DESCRIPTION:

Change the CSS properties, as specified bt **[CSSPROPERTIES]**, of all elements that match the selector in **[ELEMENTS]**. There must be exactly one **[ELEMENTS]** environment and one **[CSSPROPERTIES]** environment. The elements are typically selected from those generated by other commands.

USED IN: EICOMMAND

ADDMARKERCOMMAND

```
<addmarker outclass=[OUTCLASS]? dest=[PATH]? boxtitle=[STR]? boxwidth=[INT]? boxheight=[INT]?>
  [LINES]
  [CONTENT]*
</addmarker>
```

DESCRIPTION:

Add a marker next to each line that is specified in **[LINES]**. The column information from each **[LINE]** in **[LINES]** is ignored. All markers are associated with the content given by the **[CONTENT]** environments, as a tooltip. If the client allows expanding the tooltip to a dialog window, the the attributes **boxtitle**, **boxwidth** and **boxheight** can be used to set the properties of the corresponding window (see **[DIALOGBOX]**). The attributes **dest** and **outclass** are as described in **[EICOMMANDS]**.

USED IN: EICOMMAND

ADDINLINEMARKERCOMMAND

```
<addinlinemarker outclass=[OUTCLASS]? dest=[PATH]?>
  [LINES]
  [CONTENT]
</addinlinemarker>
```

DESCRIPTION:

Add an inline marker (a line widget) for each line that is specified by [LINES]. All line widgets will include the content specified by the [CONTENT] environments. In some clients, the supported content might be only of text format. The attributes **dest** and **outclass** are as described in [EICOMMANDS].

USED IN: **EICOMMAND**

ONCODELINECLICKACTION

```
<oncodelineclick dest=[PATH]? autoclean=[BOOL]? outclass=[OUTCLASS]?>
  [LINES]
  [CONTENT]*
  [EICOMMANDS]
</oncodelineclick>
```

DESCRIPTION:

Add markers at the the code lines specified by [LINES], such that when any is clicked the commands in [EICOMMANDS] are performed. The content given by the [CONTENT] environments is associated with the markers. The attributes **dest** and **outclass** are as described in [EIACTIONS]. Moreover, the above [EICOMMANDS] environment inherits the **dest** and **outclass** attributes of this environment.

USED IN: **EIACTION**

ONCLICKACTION

```
<onclick outclass=[OUTCLASS] autoclean=[BOOL]? >
  [ELEMENTS]
  [EICOMMANDS]
</onclick>
```

DESCRIPTION:

A click on any DOM element that matches the selector of [ELEMENTS], will execute the commands declared in [EICOMMANDS]. The attributes **dest** and **outclass** are as described in [EIACTIONS]. Moreover, the above [EICOMMANDS] environment inherits the **dest** and **outclass** attributes of this environment.

USED IN: **EIACTION**

LINES

```
<lines>
  [LINE]+
</lines>
```

DESCRIPTION:

A group of lines, typically used to specify the lines affected by an [EICOMMAND] or an [EIACTION].

USED IN: **EICOMMAND**, **EIACTION**

LINE

```
<line from=[INT] to=[INT]? fromch=[INT]? toch=[INT]? />
```

DESCRIPTION:

A region (of lines) typically used to specify the region on which the effect of an **EICOMMAND** or an **EIACTION** is applied:

- **from** is the start line.
- **to** is the end line.
- **fromch** is the where the first line starts.
- **toch** is the character (i.e., column number) where the last line ends.

The default value of **to** is as the value of **from**. The default value of **colfrom** is 0, and of **colto** is the end of the line.

USED IN: **LINES**

ELEMENTS

```
<elements>
  [SELECTOR]*
</elements>
```

DESCRIPTION:

Set of elements

USED IN: **SETCSSCOMMAND, ONCLICKACTION**

SELECTOR

```
<selector value=[STR] />
```

DESCRIPTION:

The attribute **value** must be a valid selector as in JQuery. It is used to match some DOM elements.

USED IN: **ELEMENTS**

CSSPROPERTIES

```
<cssproperties>
  [CSSPROPERTY]*
</cssproperties>
```

DESCRIPTION:

A set of CSS properties.

USED IN: **SETCSSCOMMAND**

CSSPROPERTY

```
<cssproperty name=[STR] value=[STR] />
```

DESCRIPTION:

A CSS property. The attributes **name** and this **value** should correspond to valid CSS properties.

USED IN: **PROPERTIES**

CONSOLEID

([a-z,A-Z,0-9,-,_,]+ | new | default)

The value 'new' means a new console, no reference to this console is saved. The value 'default' means the default console of the client.

PATH

a path to file, including the file name, starting from the root /_ei_files/

VERSION

x.y, where *x* is the major version number and *y* is the minor one, e.g. 1.0, 1.1, etc.

OUTCLASS

none | info | warning | error
